Histones possess a covalent mark of gene expression known as a particular histone mark. Recently, a new mark was identified on histones that correspond to a protein modification catalyzed by histone acetyltransferase (HAT). This histone modification has been termed "acetylation" to highlight its similarity to the better characterized chromatin modification by acetylation. In addition to the well characterized acetylation of lysine residues, a class of non-lysine-specific acetyltransferases was identified and its possible function was investigated. HATs are involved in a wide range of functions, such as transcriptional activation and repression, DNA repair and replication and chromatin remodeling. Although HATs were initially identified and shown to acetylate nucleosomal histones, their substrate specificity continues to expand to a variety of nucleic acid molecules. In this review, we will summarize recent advances in the field of histone acetylation, with a particular focus on its function in transcription.Q: Why does my text change after getting data from an API When I click the edit button on my modal, the text changes after I send a value to my API. Why does this happen? Not sure if it's the onClick event or the onSubmit event but this is what I've noticed happening. getEvents() function let url = '' fetch('') .then(response => response.json()) .then(data => { this.setState({ events: data }); }); Modal edit event onClick = (event) => { this.setState({ event: {...this.state.event, name: event.target.value } }); } I expect the text to change, but this happens after I click submit. A: I have got it to work by modifying the change in updateInput on the modal. constructor() { super(); this.
